

the program of DNA in that first single cell — height, hair color, eye color, sex, the design for individual features, and even much of the basic temperament is genetically determined in the formation of that first complete cell!

3 Weeks: The body is beginning to take recognizable shape, with the development of all basic organs, including the brain.

4 Weeks: There is a heartbeat.

8 Weeks: The baby is 1 1/2 inches long, has all its organs, with hands, feet, and limbs. With the means of ultrasound, fingerprints and footprints can be seen. His ears and teeth have developed.

10 Weeks: The baby is active, and the mother begins to feel its movements. It sucks its thumb, jumps, and can scratch its head.

11 Weeks: At 2 1/2 inches long, and 1 ounce in weight, the baby is a complete person. Its heart beats, its brain functions, all its involuntary body systems are in place and functioning. It sleeps, dreams, hears, feels, urinates, and has

bowel movements. It is at this age that the baby is in the greatest danger of being exterminated by a combined mother-doctor team.

4 Months: The baby frowns, turns its head, kicks its feet, grasps with its hands.

7 Months: The baby can open its eyes and respond to light. It also responds to sound.

8 Months: The body is fully developed; the number of brain cells is complete. The baby needs only a little more growth in order to safely leave its protected environment and live in the world as an individual human.

9 Months: At this point, the cerebral cortex, the part of the brain associated with thought and consciousness, is fully developed. The baby is ready to be born.

Every American would recoil in horror at the idea of concentration camps, gas chambers, or death by starvation — for adults. How can it be that masses of us have accepted the slaughter of the innocent pre-born, without a qualm of conscience? Check Jeremiah 22:3-5 and Isaiah 53:9 for God's curse on those who shed innocent blood.

The 21st Century's Holocaust

Betty Burton Choate

That well-publicized Holocaust of the 20th Century is history. It took place over sixty years ago. Men have become more civilized since then, and surely if any nation rose up again in such abuse of the human rights of its own citizens, the entire world would respond in anger to crush that nation into the dirt...

But humanity, in its pride of being civilized, and reveling in the advances of modern technology, has brainwashed itself again with the thinking of the Nazis. Among us is the reasoning that certain select people deserve to live and work and play and prosper, even if it means the death of other humans.

The methods of extermination today are not the Jewish concentration camps, or the gas chambers, or the burial of still-living humans in mass trenches. Nevertheless, the modern techniques have been well-thought-out — again, doctors and scientists have taken the lead — and the deeds are done with the latest in equipment

and technology. Consider these methods of execution:

Suction Aspiration: Using an extremely powerful suction tube with a knife-like edge on the tip, the doctor sucks the body into a container. In the process, the living human is literally pulled apart. Any shreds which remain are scraped away with the knife edge and are also sucked into the container so that the whole can be disposed of.

“D & C”: No suction is used in this procedure. The human is simply cut into small pieces and then scraped into a container.

Prostaglandin: This is a drug developed for the specific purpose of removing a human from a protected environment in which he can live, and of putting him out where he will surely die — and he *does* die, either through total neglect on the part of the doctor, or through the aid of the doctor.

Saline Poisoning: In this procedure, the human — imprisoned in a small cell — is submerged in a salt solution. He breathes it, he swallows it, he is poisoned internally by it — drowns in it — and his outer flesh is literally burned away by the concentrated salt “bath”. After suffering an excruciating death, the body

without its protective outer skin is a raw, red mass of tortured flesh.

Hysterotomy: In this method of execution, the human is taken from the atmosphere in which he was designed to live and he is thrown into one which does not supply the elements required for survival. If he does not die immediately, he may be smothered by the doctor who did the surgery of removal. Or his head may be twisted off.

The sixth method currently in use is the latest and most sophisticated in technology. A small incision is made in the back of the neck, at the base of the brain. Through a suction tube, the brain is sucked from the skull of the living human being.

Many of these bodies are sacked up in garbage bags and disposed of as refuse. However, science is learning more and more about ways to use organs and tissue from the discarded bodies. Certain tissue is useful in skin creams, advertised as having the capability of restoring the appearance of youth to aged cells. Other tissue is useful in treating Parkinson’s Disease. It has even been found that eggs taken from the ovaries of dead females can be fertilized and embryos can be developed for further research. Actually, the medical and experimental use of these executed

human beings is only beginning to be realized, so the market will flourish in years to come.

Since 1973, more than 56,000,000 people have suffered such execution in the United States. In Japan and Russia, where these practices have been legal even longer, a much larger number has died helplessly in the hands of doctors who should have been pledged to preserve life. China controls population growth through the forced murder of humans. These figures are not the exception — they are the typical story throughout the “civilized” world. Literally hundreds of millions of people have been mercilessly slaughtered by the most inhumane and criminal means during the past four decades.

Seeing Life From Conception

Until 1965 it was possible to see a human only after he was born. Then technology introduced cameras which can actually photograph the egg and the sperm as they are united to form the first cell. Every change that takes place in the development of the human body during the first nine months of existence has now been photographed. These incredible facts have been documented:

At Conception: With the union of the female egg and the male sperm, life begins. Every particle of the adult human is contained in
